description

The TL520, TL521, and TL522 are monolithic CMOS devices each with an 8-channel multiplexer, and 8-bit analog-to-digital (A/D) converter, and microprocessor-compatible control logic. The 8-channel multiplexer can be controlled by a microprocessor through a 3-bit address decoder with address load to select any one of eight single-ended analog switches connected directly to a comparator. The 8-bit A/D converter uses a binary-weighted capacitor array to implement the high-speed, successive-approximation conversion technique.

The comparison and conversion methods used eliminate the possibility of missing codes, nonmonotonicity, and the need for zero or full-scale adjustment. Also featured are latched 3-state outputs and latched inputs to the multiplexer address decoder. The single 5-volt supply and low power requirements make the TL520 and TL521 especially useful for a wide variety of applications. The 3-volt and low power requirements make the TL522 especially useful for battery and LCD applications. Ratiometric conversion is made possible by access to the reference voltage input terminals.

The TL520, TL521, and TL522 are characterized for operation from -40°C to 85°C .

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Supply voltage, V_{CC} (see Note 1)	6.5 V
Positive reference input voltage range, V_{REF+}	V_{REF-} to $V_{CC} + 0.3$ V
Negative reference input voltage range, V_{REF-} (see Note 1)	-0.3 V to V_{REF+}
Input voltage range: all other inputs	-0.3 V to $V_{CC} + 0.3$ V
Continuous total dissipation at 25°C free-air temperature (see Note 2)	1250 mW
Operating free-air temperature range	-40°C to 85°C
Storage temperature range	-65°C to 150°C
Lead temperature 1.6 mm ($1/16$ inch) from case for 10 seconds	260°C

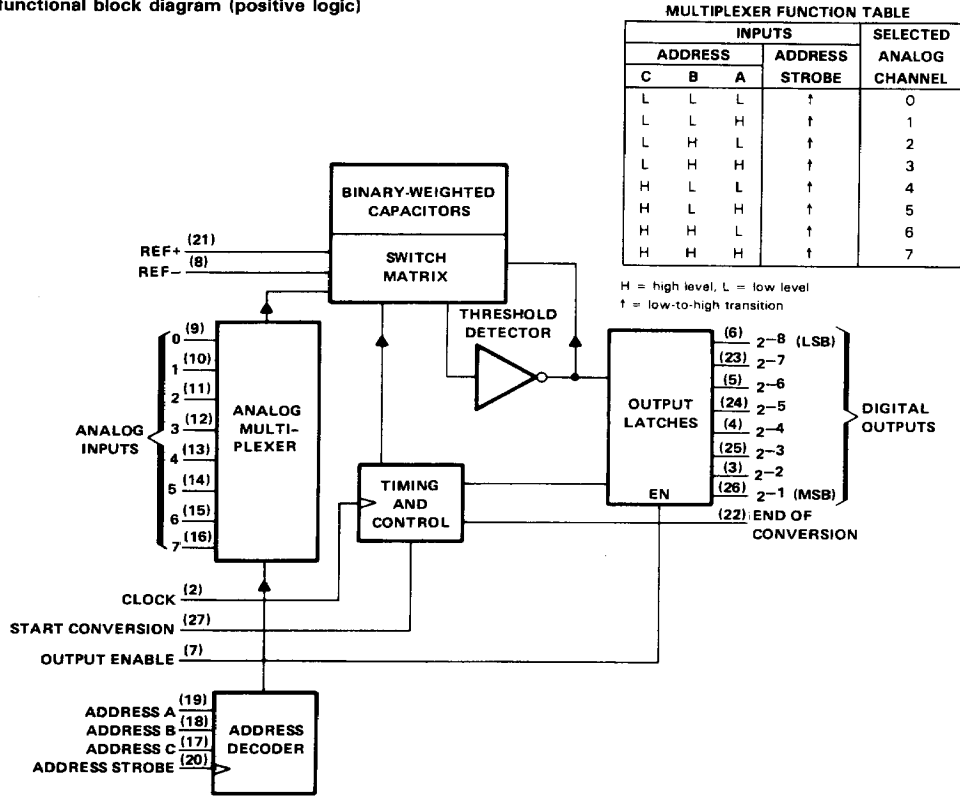

NOTES: 1. All voltage values are with respect to network ground terminal.
 2. For operation above 25°C free-air temperature, refer to Dissipation Derating Curves, Section 2.

Operating free-air temperature, T_A	-40			85			$^{\circ}$ C

TL522 recommended operating conditions

	MIN	NOM	MAX	UNIT	
Supply voltage, V_{CC} (see Note 4)	$T_A = 0^{\circ}$ C to 85° C			V	
	$T_A = -40^{\circ}$ C to 0° C				
Positive reference voltage, V_{REF+} (see Notes 3 and 4)	2.75	3	5.5	V	
Negative reference voltage, V_{REF-} (see Note 3)	0		0.3	V	
Supply voltage relative to V_{REF+} , $V_{CC} - V_{REF+}$	0		1	V	
Analog input voltage (see Note 3)	V_{REF-}		V_{REF+}	V	
High-level control input voltage, V_{IH}	0.7 V_{CC}			V	
Low-level control input voltage, V_{IL}	0.3 V_{CC}			V	
Clock frequency, f_{clock}	$V_{REF+} = 5$ V			kHz	
	$V_{REF+} = 2.75$ V (see Note 4)				
Conversion time, t_{conv} (see Note 5)	200			μ s	
Duration of start pulse, $t_w(S)$	600			ns	
Duration of address strobe pulse, $t_w(AS)$	600			ns	
Address setup time, t_{su}	200			ns	
Address hold time, t_h	150			ns	
Input voltage hold time	8			clock periods	
Operating free-air temperature, T_A (see Note 4)	-40			85	$^{\circ}$ C

- NOTES: 3. Analog input voltage greater than V_{REF+} converts as all highs and less than V_{REF-} converts as all lows.
4. For proper operation of TL522 at free-air temperatures below 0° C, V_{CC} and differential reference voltage ($V_{REF+} - V_{REF-}$) must never be less than 3 volts.
5. Conversion time is a function of clock frequency, with 200 μ s corresponding to a maximum clock frequency of 130 kHz.

timing diagram

PRINCIPLES OF OPERATION

timing diagram

The analog multiplexer selects 1 of 8 single-ended input channels as determined by the input address code. The address strobe transfers and latches the address into the decoder on the positive-going edge of the signal. The output latch is reset by the positive-going edge of the start pulse. Sampling also starts with the positive-going edge of the start pulse and lasts for 8 clock periods. The conversion process may be interrupted by a new start pulse before the end of 24 clock periods. The previous data will be lost if a new start of conversion occurs before the 24th clock pulse. Continuous conversion may be accomplished by connecting the end-of-conversion output to the start input. If used in this mode an external pulse should be applied after power up to assure start up.

converter

The CMOS threshold detector in the successive-approximation conversion system determines each bit by examining the charge on a series of binary-weighted capacitors (Figure 1). In the first phase of the conversion process, the analog input is sampled by closing switch S_C and all S_T switches, and by simultaneously charging all the capacitors to the input voltage.

In the next phase of the conversion process, all S_T and S_C switches are opened and the threshold detector begins identifying bits by identifying the charge (voltage) on each capacitor relative to the reference voltage. In the switching sequence, all eight capacitors are examined separately until all 8 bits are identified, and then the charge-convert sequence is repeated. In the first step of the conversion phase, the threshold detector looks at the first capacitor (weight = 128). Node 128 of this capacitor is switched to the reference voltage, and the equivalent nodes of all the other capacitors on the ladder are switched to REF - . If the voltage at the summing node is greater than the trip-point of the threshold detector (approximately one-half the reference voltage), a bit is placed in the output register, and the 128-weight capacitor is switched to REF - . If the voltage at the summing node is less than the trip point of the threshold detector, this 128-weight capacitor remains connected to REF + through the remainder of the capacitor-sampling (bit-counting) process. The process is repeated for the 64-weight capacitor, the 32-weight capacitor, and so forth down the line, until all bits are counted.

With each step of the capacitor-sampling process, the initial charge is redistributed among the capacitors. The conversion process is successive approximation, but relies on charge shifting rather than a successive-approximation register (and reference D/A) to count and weigh the bits from MSB to LSB.

TYPES TL520, TL521, TL522
CMOS ANALOG-TO-DIGITAL CONVERTERS
WITH 8-CHANNEL MULTIPLEXERS

TYPICAL APPLICATION INFORMATION

The TL520, TL521, and TL522 are CMOS devices using charge redistribution to achieve A/D conversion. In typical applications as a ratiometric conversion system for a microprocessor, REF- will be connected to ground and REF+ will be connected to VCC. The output will then be a simple proportional ratio between the analog input voltage and VCC (Figure 3). The general relationship is

$$\frac{D_{out}}{2^8} = \frac{V_{in}}{V_{REF+} - V_{REF-}}$$

where D_{out} = decimal value of binary output word
 V_{in} = analog input voltage
 V_{REF+} = positive reference voltage = V_{CC}
 V_{REF-} = negative reference voltage = V_{GND}

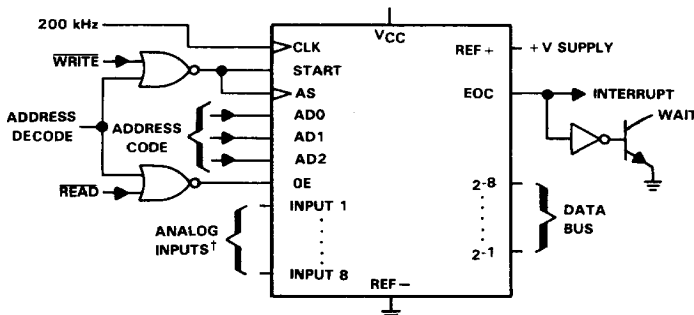

Latchup may overheat and destroy the device and may occur by either of two kinds of circumstances: out of range reference voltages or by incorrect power-up sequence. V_{REF+} should not be more positive than V_{CC} by more than 300 millivolts or V_{REF-} should not be more negative than GND by more than 300 millivolts. Apply V_{CC} before either of the reference voltages. The advantage of the compressed reference potential is that the full 8-bit resolution applies to be compressed voltage range (Figure 4). However, the cautions mentioned above must be observed. Operation at voltages down to $V_{CC} = 3$ volts is possible but limits the frequency to 100 kilohertz maximum and thus conversion time to 260 microseconds minimum. Interface for the common microprocessors is shown in Figure 2.

MICROPROCESSOR INTERFACE TABLE

PROCESSOR	READ	WRITE	INTERRUPT (COMMENT)
TMS7000	RD	WR	EINT
TMS9900	MEMEN	WE	INTREQ
8080	MEMR	MEMW	INTR (Thru RST Circuit)
8085	RD	WR	INTR (Thru RST Circuit)
Z-80	RD	WR	INT (Thru RST Circuit, Mode 0)
